

Potential Native Trees For Georgia Hardiness Zone 9a

Dr. Kim D. Coder, Professor of Tree Biology & Health Care / University Hill Fellow
University of Georgia Warnell School of Forestry & Natural Resources

Native trees represent a great ecological bounty and a rich cultural history in Georgia. Native trees live from the mountains to the sea in many diverse habitats and under many environmental constraints. Native trees are wonderfully adapted to a local area's climate, soils, pests and other plants. What happens to tree growth ranges and survival patterns when climate changes?

Success Mapping

One standard means of describing where trees are growing and will grow, and where to plant different tree species, involves measuring the average annual minimum temperature. A map showing areas with similar minimum temperatures is termed a hardiness zone map.

Several organizations have generated these type of maps over many years, but the most cited map is the USDA Plant Hardiness Zone Map. This map is used by nurseries, planting reference manuals, and by tree selection specialists for estimating whether a tree will survive and grow in a particular area. Hardiness zone maps are periodically changed in association with changing climate temperature values.

Decade of Change

Over the last decade, average annual minimum temperatures have changed significantly across the nation and within Georgia. Figure 1. Some hardiness zones have shifted more than five counties northward in Georgia. These climate shifts have impacted, and will impact, planted tree species survival and growth, the pantheon of pests potentially damaging these trees, and existing tree and pest species, as well as exacerbating some abiotic stress problems. Tree health can be affected in significant ways by large hardiness zone shifts.

New Hardiness Zone 9a

The current (January 2012) hardiness zone map added, essentially for the first time, hardiness zone 9a to Georgia. Figure 2. All or part of five coastal counties are now included in hardiness zone 9a. Traditionally, zone 9a was considered the North-central and central Florida zone. This additional zone in Georgia represents a full 5°F increase in average annual minimum temperatures.

Hardiness zone changes will influence tree selection, new tree survival, and new pest regimes for the Georgia coast. Long term impacts of this change in hardiness zones will also shift native tree population ranges into new areas. Note this list does not include exotic tree invaders and invasives which could naturalize within zone 9a in Georgia.

Always Changing !

Change is an ecological fact of life for our forest and community trees. Climatic change will continue. Over the last 2,000 years, 20,000 years, 200,000 years, and 2 million years there have been large climatic changes impacting trees. Hardiness zone changes represent an opportunity for exploring new tree species plantings, as well as northward expanding ranges for some trees native to hardiness zone 9a.
